This Protocol considers this test or procedure investigational. If the physician feels this service is medically necessary, preauthorization is recommended.

The following Protocol contains medical necessity criteria that apply for this service. The criteria are also applicable to services provided in the local Medicare Advantage operating area for those members, unless separate Medicare Advantage criteria are indicated. If the criteria are not met, reimbursement will be denied and the patient cannot be billed. Please note that payment for covered services is subject to eligibility and the limitations noted in the patient’s contract at the time the services are rendered.

Description

Several commercially available laboratory tests assess heart transplant rejection, including the Heartsbreath™ test, which measures breath markers of oxidative stress, and the AlloMap™ test, which uses gene expression profiling (GEP) to create a score based on the expression of a variety of immunomodulatory genes. These tests are proposed as an alternative to, or adjunct to, endomyocardial biopsy, which is invasive, and its interpretation may have high interobserver variability.

Summary of Evidence

There is insufficient evidence on the diagnostic accuracy of the Heartsbreath test, especially for grades 3 and 4 rejection, and no published studies have evaluated the clinical utility of this test. Therefore, the use of the Heartsbreath test to assist in the detection of heart transplant rejection is considered investigational.

There is some evidence on the diagnostic accuracy of the AlloMap test from the CARGO trial and post-CARGO publications. However, the evidence is not sufficiently rigorous to determine the true sensitivity and specificity of the test with certainty. The clinical utility of the AlloMap test compared with routine endomyocardial biopsies has been evaluated in two subsequent randomized controlled trials (RCTs), the IMAGE study in patients more than six months posttransplant, and a small pilot RCT in patients starting at 55 days posttransplant. The threshold indicating a positive test that seems to be currently accepted, a score of 34, evolved partway through the data collection period of the IMAGE study. In addition, the IMAGE study had several methodologic limitations, e.g., lack of blinding, and it was not able to determine whether AlloMap offers incremental benefit compared with biopsy performed on the basis of clinical exam and echocardiography. In patients at less than one year after transplant, the group that is at highest risk of transplant rejection, there are insufficient data on the clinical utility of AlloMap. Results from a pilot RCT suggest that AlloMap may be noninferior to a strategy of routine biopsies for heart-detecting transplant rejection beginning at 55 days posttransplant, but the study was insufficiently powered to allow firm conclusions. Thus, use of the AlloMap test to assist in the detection of heart transplant rejection is considered investigational.
Policy

The measurement of volatile organic compounds with the Heartsbreath test to assist in the detection of grade 3 heart transplant rejection is considered investigational.

The use of peripheral blood genetic profiling tests in the management of patients after heart transplantation, including but not limited to the detection of acute heart transplant rejection or heart transplant graft dysfunction, is considered investigational.

Policy Guidelines

The U.S. Food and Drug Administration (FDA) has indicated that the Heartsbreath test is only for use as an aid in the diagnosis of grade 3 heart transplant rejection in patients who have received heart transplants within the preceding year and who have had endomyocardial biopsy within the previous month.

Medicare Advantage

AlloMap™ may be considered medically necessary for the FDA approved indication to aid in the identification of heart transplant recipients with stable allograft function who have a low probability of moderate/severe acute cellular rejection (ACR) at the time of testing in conjunction with standard clinical assessment.

Any other uses of Allomap are considered investigational.

The Heartsbreath™ test is considered investigational.

Background

Heart Transplant Rejection

Most cardiac transplant recipients experience at least one episode of rejection in the first year after transplantation. Acute cellular rejection is most likely to occur in the first six months, with a significant decline in the incidence of rejection after this time. Although immunosuppressants are required on a life-long basis, dosing is adjusted based on graft function and the grade of acute cellular rejection determined by histopathology. Endomyocardial biopsies are typically taken from the right ventricle via the jugular vein periodically during the first six to 12 months posttransplant. The interval between biopsies varies among clinical centers. A typical schedule is weekly for the first month, once or twice monthly for the following six months, and several times (monthly to quarterly) between six months and one year posttransplant. Surveillance biopsies may also be performed after the first postoperative year, e.g., on a quarterly or semiannual basis. This practice, although common, has not been demonstrated to improve transplant outcomes. Some centers no longer routinely perform endomyocardial biopsies after one year in patients who are clinically stable.

While endomyocardial biopsy is the criterion standard for assessing heart transplant rejection, it is limited by a high degree of interobserver variability in grading of results and potential morbidity that can occur with the biopsy procedure. Also, the severity of rejection may not always coincide with the grading of the rejection by biopsy. Finally, biopsy cannot be used to identify patients at risk of rejection, limiting the ability to initiate therapy to interrupt the development of rejection. For these reasons, endomyocardial biopsy is considered a flawed criterion standard by many. Therefore, noninvasive methods of detecting cellular rejection have been explored. It is hoped that noninvasive tests will assist in determining appropriate patient management and avoid overuse or underuse of treatment with steroids and other immunosuppressants that can occur with false-negative and false-positive biopsy reports. Two techniques have become commercially available for the detection of heart transplant rejection.
Noninvasive Heart Transplant Rejection Tests

The Heartsbreath™ test (Menssana Research, Newark, NJ), a noninvasive test that measures breath markers of oxidative stress, has been developed to assist in the detection of heart transplant rejection. In heart transplant recipients, oxidative stress appears to accompany allograft rejection, which degrades membrane polyunsaturated fatty acids and evolving alkanes and methylalkanes that are, in turn excreted as volatile organic compounds in breath. The Heartsbreath test analyzes the breath methylated alkane contour, which is derived from the abundance of C4 to C20 alkanes and monomethylalkanes and has been identified as a marker to detect grade 3 (clinically significant) heart transplant rejection.

Another approach has focused on patterns of gene expression of immunomodulatory cells, as detected in the peripheral blood. For example, microarray technology permits the analysis of the gene expression of thousands of genes, including those with functions that are known or unknown. Patterns of gene expression can then be correlated with known clinical conditions, permitting a selection of a finite number of genes to compose a custom multigene test panel, which then can be evaluated using polymerase chain reaction (PCR) techniques. AlloMap™ (CareDx, Brisbane, CA; formerly XDx Inc.) is a commercially available molecular expression test that has been developed to detect acute heart transplant rejection or the development of graft dysfunction. The test involves PCR-expression measurement of a panel of genes derived from peripheral blood cells and applies an algorithm to the results. The proprietary algorithm produces a single score that considers the contribution of each gene in the panel. The score ranges from zero to 40. The XDx website states that a lower score indicates a lower risk of graft rejection; the website does not cite a specific cutoff for a positive test. All AlloMap testing is performed at the CareDx reference laboratory in Brisbane, California.

Other laboratory-tested biomarkers of heart transplant rejection have been evaluated. These include brain natriuretic peptide, troponin, and soluble inflammatory cytokines. Most of these have had low diagnostic accuracy in diagnosing rejection. Preliminary studies have evaluated the association between heart transplant rejection and micro-RNAs or high-sensitivity cardiac troponin in cross-sectional analyses, but the clinical use has not been evaluated.

Regulatory Status

In February 2004, the Heartsbreath test (Menssana Research) received approval from FDA through a Humanitarian Device Exemption. The Heartsbreath test is indicated for use as an aid in the diagnosis of grade 3 heart transplant rejection in patients who have received heart transplants within the preceding year. The device is intended to be used as an adjunct to, and not as a substitute for, endomyocardial biopsy and is also limited to patients who have had endomyocardial biopsy within the previous month.

In August 2008, AlloMap Molecular Expression Testing (CareDx, Brisbane, CA; formerly XDx Inc.) was cleared for marketing by FDA through the 510(k) process. FDA determined that this device was substantially equivalent to existing devices, in conjunction with clinical assessment, for aiding in the identification of heart transplant recipients with stable allograft function who have a low probability of moderate/severe transplant rejection. It is intended for patients at least 15 years old who are at least two months posttransplant.
